Is There A Methadone Equivalent For Alcoholics?

By The Professionals At Robert Alexander Center

Many alcoholics we know seem to experience a rebound effect when they quit drinking. They might feel better for the first few days and then back again, or they may be able to take it or leave it. The problem is that when people do not drink, their body still craves alcohol which can lead to binge drinking when the person has been sober for too long. This will lead to severe withdrawal symptoms causing an outrageous amount of discomfort for anyone experiencing it. Is there an equivalent of methadone that can be given to someone who is trying to stop drinking? This article will take a look at what can be done to assist family members in this type of distress.

How Can Methadone Help Alcoholics?

Methadone does not affect the brain in the same way as alcohol, but it can be given to people trying to stop drinking. It is most often used for opiate addiction like heroin or pain pill abuse; however, many doctors now believe that methadone may also help with alcoholism. Alcoholism is an addictive disorder, and both of these conditions have some similar symptoms, including cravings for more drugs/drinks, which is why Methadone works well with this type of addiction. In addition, this medication helps prevent withdrawal symptoms so patients will not feel anxious when they quit drinking or using other substances because their body has become accustomed to receiving them regularly.

Is There a Methadone Equivalent for Alcoholics

Methadone is not the only way to treat alcoholism. A doctor can prescribe other methods like Antabuse, which makes it impossible for people to drink even though they might want to. Another medication that may work better than Methadone with alcoholics is Naltrexone; this drug works in the brain and helps prevent cravings, so there is no need for opiate blockers like Antabuse because opioid receptors will not receive any signals of reward when someone takes this particular medication. Alcoholism has many symptoms, including relapse prevention, anxiety, or depression-related issues; therefore, if one type of treatment does not seem to help, another alternative should be considered before quitting entirely on your own without using medications as part of a plan to stop drinking.

The Benefits of Methadone

Methadone is a narcotic drug that works in the brain to prevent withdrawal symptoms. It can be administered for different purposes such as pain management, relapse prevention, and treatment of addiction-related disorders like alcoholism or opiate dependence. It comes in pill form, but it may also be injected into muscle tissue, under the skin, or inside veins (intravenously). This medication has been used since 1947. The difference between methadone and alcohol is that when someone takes methadone, they do not experience an intoxicating high because there are no opioids in this particular medication; however, people who take it will feel contented, which is why some call Methadone "the happy juice."

What are the Benefits of Methadone Treatment

If you are trying to stop drinking, then Methadone is not the only way that can help. There are other medications like Naltrexone that work similarly but do not contain any opioids. It has fewer side effects than Methadone; however, there may be certain benefits of taking methadone for alcoholism compared to some traditional treatments. One example is detoxification because this medication helps reduce withdrawal symptoms. Someone who quits drinking will feel better during their first few days without alcohol rather than feeling awful as if they were going through withdrawals on their own. Also, people who take methadone do not experience an intoxicating high when they drink or use drugs because opioid receptors do not receive any reward signals. This can help prevent a relapse because someone might be more likely to drink again if they do not feel any effects from alcohol or drugs when they have been taking Methadone for some time and then decide to stop entirely on their own without support from their doctor.

In conclusion, Methadone works well for alcoholics because it helps prevent withdrawal symptoms which is why many call Methadone "the happy juice." It can be administered orally or via injection into muscle tissue, under the skin, or inside veins (intravenously). This will not only see to it that patients recover without too many withdrawal symptoms but also ensure patients are able to navigate through this utmost of difficult times and remain strong enough not to relapse.
