

Is Adderall Addictive?

by Robert Alexander Center | Apr 18, 2022 | Blog | 0 comments

As one of the most commonly prescribed ADHD medications, you may be wondering if Adderall is addictive. The answer is yes; it most certainly is. Adderall comes with warnings of a “high potential for abuse” and is closely monitored by prescribers.

Individuals who abuse Adderall need to get medical help through rehabilitation immediately. As a stimulant, Adderall is unpredictable and can damage the body irreparably when misused.

What is Adderall?

Adderall is a medication prescribed to help individuals with Attention Deficit Hyperactivity Disorder and can also be used to treat narcolepsy. This drug is designed to increase the release of dopamine and norepinephrine. Dopamine impacts the brain's reward center through this process, while norepinephrine increases functions like heart rate and blood pressure.

Taking this prescription can cause an individual to feel a rush and increase breathing, blood pressure, heart rate, increased blood sugar, and opened-up breathing passages. However, it can also cause a decrease in blood flow, causing parts of the body to get cold more quickly or feel as if they've fallen asleep.

Is Adderall Addictive?

Adderall is addictive. Adderall is made from the drugs dextroamphetamine and amphetamine. These drug names sound familiar because they are related to the commonly abused illegal drug, methamphetamine. Amphetamines are the stimulant portion of the drugs that cause the body to speed up and produce an excessive release of dopamine and norepinephrine.

Adderall addiction occurs through the misuse of the prescription or the development of tolerance to the stimulant. Abuse occurs when individuals take Adderall to get high, take it with other contraindicated drugs, alter how it is taken to make it work more quickly, or take more than the recommended dose. Tolerance to Adderall can occur when an individual takes the drug for an extended time, and it no longer has the same effects as it once did. Through both of these processes, an individual should contact their physician to talk about possible rehabilitation or changes to the medication.

How Does Adderall Impact the Body?

While Adderall is designed to help the brain focus and help those with narcolepsy stay awake, it can negatively impact the body. On the FDA access sheet, Adderall dependency warnings include serious cardiovascular events, sudden death in those with heart abnormalities or other serious heart problems, hypertension, pre-existing psychosis, bipolar illness, manic symptoms, aggression, long-term suppression of growth, seizures, and visual disturbances.

What are the Symptoms of Adderall Addiction?

Symptoms of Adderall addiction don't just impact the individual at home; they are pervasive and cause an impact at school or work as well. In addition, individuals who struggle with addiction are affected socially and personally by the habits created through misuse.

By misusing Adderall, individuals open themselves up to a host of additional symptoms related to the abuse of stimulant drugs. An acute overdose of Adderall can cause restlessness, tremors, rapid breathing, confusion, and hallucinations. These symptoms will persist and worsen if an individual does not stop using Adderall.

When an individual takes too much Adderall, they can have symptoms that include insomnia, irritability, hyperactivity, and personality changes. The most severe manifestation of chronic intoxication is psychosis, often clinically indistinguishable from schizophrenia.

Individuals who stop using Adderall after becoming addicted will experience a withdrawal period that can include fatigue, depression, and sleep disturbances. These will eventually wear off, but cravings for the drug can persist.

How to Find Adderall Addiction Treatment

The best way to find Adderall addiction treatment in your area is by talking with your physician about your Adderall use. This prescription drug is highly addictive, so that physicians will be prepared with recommendations.
